Implementing Network Servers and Clients

The net module

The net module is used to implement network servers or clients. It supports IPv4 as well as IPv6.

Creating network servers

bind(hostname, port)

Bind a socket on the specified hostname and port. This also does the listen system call.

sock:accept()

Accept a new connection and return a new socket for the new connection.

sock:close()

Close a socket.

Creating network clients

connect(hostname, port)

Connect to hostname at the specified port and return a new socket.

Transferring data

sock:write(data)

Write data to the socket.

sock:print(string)

Write string to the socket and append a newline character.

sock:read([timeout])

Read data from a socket with an optional timeout in milliseconds. Returns the data read or nil if the timeout expires or an error occured.

sock:readln([timeout])

Read data up to the first newline character from a socket with an optional timeout in milliseconds. Returns the data read or nil if the timeout expires or an error occured.

sock:socket()

Return as an integer the underlying socket.

sock:close()

Close a socket.
